

# Research and Implementation of Multi-Dataset Training for Image Classification with Discrepant Taxonomies

Master Thesis Presentation

Björn Buschkämper

Technical Faculty, Bielefeld University

September 19, 2025

# Outline

- 1 Introduction & Motivation
- 2 Method Overview
- 3 Universal Model
- 4 Results
- 5 Conclusion

# The Challenge: Limited Scope of Traditional Models

- Traditional image classification models are trained on specific datasets
- Each model recognizes only a predefined set of categories
- Multiple models needed for different domains = inefficient storage and deployment

## Current Approaches:

- **Transfer Learning:** Adapt pre-trained models to new tasks
- **Multi-head Architecture:** Shared backbone + task-specific heads

**Problem:** Still requires separate models or heads for each domain

# Our Idea: Universal Model vs. Multi-Head

## Multi-Head Approach

- Shared backbone
- Task-specific heads
- Automatic feature distillation
- Domain alignment challenges

## Universal Model Approach

- Single shared model
- Universal output layer
- Predefined concept mapping
- Static domain conversion

**Our task:** Discover inter-dataset class relationships to build a universal taxonomy

# Our Method in 3 Steps

- 1 **Cross-Domain Prediction:** Train domain-specific models, run inference on other domains
- 2 **Relationship Building:** Extract meaningful relationships from cross-domain predictions and create universal taxonomy
- 3 **Universal Model Training:** Create and train a single model using universal taxonomy

# Changes to Method of Bevandic et al.

- ① **Weighted Relationships:** Instead of binary, unweighted relationships, we use weighted relationships to capture the strength of associations between classes.
- ② **Relationship Selection Methods:** We try multiple methods to select the most relevant relationships from noisy cross-domain predictions.
- ③ **Discrete Probability Loss Function:** We use a loss function that allows training with probability distributions as targets, enabling the model to learn from the uncertainty in class relationships.
- ④ **Adapted to Image Classification:** The original method was designed for image segmentation, we adapt it for image classification tasks.

# Cross-Domain Prediction Process

**Goal:** Discover relationships between classes from different datasets

**Process:**

- 1 Train domain-specific models
- 2 Run each model on images from *all other* domains, building prediction matrices  $M_{ab}(i, j)$   
= number of times class  $c_i^a$  predicted as class  $c_j^b$
- 3 Create probability matrices  $P_{ab}(i, j)$  = probability of classifying class  $c_i^a$  as class  $c_j^b$

$$P_{ab}(i, j) = \frac{M_{ab}(i, j)}{\sum_{k=1}^{|C_a|} M_{ab}(i, k)} \quad (1)$$

**Example:** Caltech-256 class "car" predicated by CIFAR-100 model as "vehicle" (80%), "bike" (18%), "butterfly" (2%)

# Challenge: Selecting Relevant Relationships

## Problems with raw probability matrices:

- Noisy predictions from imperfect models
- Unknown number of true relationships
- Different datasets have different scales of similarity

**Solution:** Develop multiple relationship selection methods and compare their effectiveness

# Relationship Selection Methods Explained

## ① Most Common Foreign Prediction (MCFP) by Bevandic et al.:

$$\text{select\_relationships}(P_{ab}) = \{(i, j) \mid j = \operatorname{argmax}_{j'} P_{ab}(i, j')\} \quad (2)$$

## ② Naive Thresholding:

$$\text{select\_relationships}(P_{ab}) = \{(i, j) \mid P_{ab}(i, j) \geq t\} \quad (3)$$

## ③ Density Thresholding: Select minimum relationships covering $p\%$ of probability mass

## ④ Relationship Hypothesis: Assumes relationships based on shared concepts should have equal probabilities. For each class, find optimal $k$ relationships by minimizing:

$$\sum_{j=1}^k \left| X_i(j) - \frac{1}{k} \right| + \sum_{j=k+1}^{|C_b|} X_i(j) \quad (4)$$

where  $X_i(j)$  are sorted probabilities in descending order.

## How do we convert relationship graphs into universal taxonomies?

- ❶ **Isolated Node Rule:** Classes with no relationships
  - Create new universal class for standalone domain classes
  - Ensures all classes are represented in universal taxonomy
- ❷ **Bidirectional Relationship Rule:** Classes with mutual relationships ( $A \leftrightarrow B$ )
  - Create single universal class  $C$  with relationships  $A \rightarrow C$ ,  $B \rightarrow C$
  - Indicates classes likely represent the same concept
- ❸ **Transitive Cycle Rule:** Prevent invalid cycles ( $A \rightarrow B \rightarrow C$  where  $A, C$  same domain)
  - Remove relationship with lower probability
  - Classes within same domain should be disjoint
- ❹ **Unilateral Relationship Rule:** Handle subset relationships ( $A \rightarrow B$ )
  - Create universal class for shared concepts ( $A \cup B$ )
  - Create universal class for unique concepts ( $B$  only)

# Taxonomy Visualization (Caltech-101 + Caltech-256)

# Good Cluster

# Bad Cluster

# Building the Universal Model

- Every universal class corresponds to one output neuron
- Each domain class maps to one or more universal classes
- Matrix  $M_i$  maps domain  $i$  classes to universal classes

**Target Generation:** Convert domain labels to universal class distributions

$$\mathbf{t} = \hat{M}_i[j, :] \quad \text{where} \quad \hat{M}_i(j, u) = \frac{M_i(j, u)}{\sum_{u'} M_i(j, u')} \quad (5)$$

**Loss Function:**

$$\mathcal{L} = - \sum_{u=1}^{|U|} \mathbf{t}(u) \log(\mathbf{p}(u)) \quad (6)$$

# Multi-Domain Training Process

## Training Procedure:

- 1 Concatenate domain datasets
- 2 Each sample:  $(\text{image}, (\text{domain\_id}, \text{label})) \rightarrow (\text{image}, \text{universal\_target})$
- 3 Train universal model on unified dataset

## Inference:

$$\mathbf{d}_i = M_i^T \mathbf{p} \quad (7)$$

$$\hat{c}_i = \text{argmax}(\mathbf{d}_i) \quad (8)$$

where  $\mathbf{p}$  are universal class predictions and  $\hat{c}_i$  is the predicted class in domain  $i$ .

# Universal Model Performance

**Datasets:** Caltech-101, Caltech-256, CIFAR-100

## Cal-101 + Cal-256 Results

Taxonomy	Cal-101	Cal-256
Hypothesis	91.81 (+0.00)	82.84 (+13.36)
MCFP	91.23 (-0.58)	80.75 (+11.27)
MCFP Binary	92.73 (+0.92)	<b>89.71 (+20.23)</b>
Density	92.96 (+1.15)	81.54 (+12.06)
Naive	<b>93.19 (+1.38)</b>	82.25 (+12.77)

## Cal-101 + Cal-256 + CIFAR Results

Taxonomy	Cal-101	Cal-256	CIFAR
Hypothesis	68.74 (-23.07)	58.17 (-11.31)	69.03 (+8.55)
MCFP	83.28 (-8.53)	76.50 (+7.02)	76.10 (+15.62)
MCFP Binary	94.58 (+2.77)	85.13 (+15.65)	82.71 (+22.23)
Density	95.39 (+3.58)	83.53 (+14.05)	<b>83.14 (+22.66)</b>
Naive	<b>95.50 (+3.69)</b>	<b>85.36 (+15.88)</b>	72.56 (+12.08)

**Baselines:** Cal-101: 91.81%, Cal-256: 69.48%, CIFAR-100: 60.48%

## Key Findings:

- Universal models **outperform** single-domain baselines
- Different relationship selection methods excel on different datasets

- ➊ **Novel Weighted Graph Approach:** We have a *weighted* relationship graph instead of binary edges
- ➋ **Comprehensive Relationship Selection Methods:** Four different methods to select relevant relationships from noisy predictions
- ➌ **Reusable Taxonomy Framework:** Our code is adaptable to new taxonomy building rules, relationship selection methods, datasets and model architectures
- ➍ **Full-automatic, multi-dataset training pipeline:** We provide a complete pipeline for training on multiple datasets without manual intervention or preprocessing

## Findings:

- Bad clusters still exist in universal taxonomies
- Multi-domain universal model training outperforms single-domain training
- No single relationship selection method is best for all cases

## Future Work:

- Adaptive or hybrid relationship selection method to get best performance
- Extended tests on larger, more diverse taxonomies and datasets
- Application to other tasks (e.g., object detection, image segmentation)
